

Take-home technical exercise: Store daily sales summary

Context

You are given store reference data & a set of sales transactions. Each transaction represents a completed invoice at a company store.

Your task is to write a Python program that reads both inputs, joins them & produces a daily summary of sales metrics per store.

Expected effort

Please aim to spend **no more than 4 hours** on this exercise.

You are not expected to produce a fully polished or complete solution. Focus on a clear, pragmatic approach & prioritise readability, structure & sensible trade-offs within the time available.

Inputs

You are provided with:

1. `stores.csv`
A small reference file containing store details.
 2. `sales_transactions.json`
A JSON array of sales transaction records.
-

Required output

Produce a daily summary report per store including:

- `date`
- `store_id`
- `store_name`
- `total_sales_nzd`
- `unique_customers`
- `average_invoice_nzd`
- `max_invoice_nzd`
- `min_invoice_nzd`

You may output this as CSV, JSON or a clearly formatted table.

Business rules

- All amounts are NZD
 - Use `net_amount` as the transaction value
 - Only include transactions that can be matched to a known store
 - Deduplicate transactions using `transaction_id`
 - `unique_customers` means distinct `customer_id` values per store per day
-

What to submit

Please submit:

- A link to a Git repository containing your Python solution
- Instructions on how to clone & run the solution
- The generated output

Please ensure the repository is accessible to reviewers.

Use of AI tools

Use of AI tools is explicitly permitted.

If you use AI tools, please be prepared to discuss:

- how you used them
 - how you checked or validated the output
 - which suggestions you accepted, changed or rejected
-

Follow-up discussion

A follow-up session will be conducted as an interactive discussion where you walk through your solution.

You may be asked to:

- explain design decisions & trade-offs
- respond to new requirements or constraints
